Grow rocks often contain micro-pore spaces. These micro-pores can be pre-treated with beneficial microbial inoculants prior to transplant freshly rooted cuttings or young seedlings.

To accomplish this, pre-soak lecca stone and similar materials in a bucket of solution containing beneficial fungi and super-bacteria along with humic, fulvic and vitamins; these can be found as combined products in some 100 per cent organic additives. Add the growing medium and gently aerate. About four hours or so is typically long enough; remember those microbes want to live with roots, not under-water!

Discard the pre-soak solution on house plants or outdoor soil plants.
